UNITED STATES PATENT APPLICATION FOR

CLASS LOADING IN A VIRTUAL MACHINE
FOR A PLATFORM HAVING MINIMAL RESOURCES

Inventors:
Venkatesh Krishnan
Geetha Manjunath
K.S. Venugopal

BACKGROUND OF THE INVENTION

Field of Invention

5 The present invention pertains to the field of
processing systems. More particularly, this
invention relates to class loading by a virtual
machine.

Art Background

10 Computer systems and devices having embedded
processing resources typically conform to one of a
variety of differing architectures. Each
architecture is usually defined by a particular
instruction set, hardware register set, and memory
15 arrangement, etc. An architecture may also be
referred to as a hardware platform for software
execution. Software such as application programs
which are written or compiled to be executed on a
particular hardware platform may be referred to as
20 native code. An application program in the native
code of a particular hardware platform usually does
not run on other non compatible hardware platforms.

25 Some software environments enable application
programs to execute on a variety of differing
hardware platforms. Typically, such a software
environment provides a set of predefined services
which are specified in terms of application
programming interfaces (APIs). Such a software
30 environment is commonly implemented in an object-
oriented programming language in which the predefined
services are implemented as predefined classes.

666060" 95249360

One example of such a software environment is a Java virtual machine. A typical Java virtual machine supports a set of predefined classes. Typically, a Java virtual machine includes a class loader that loads the predefined classes into memory as needed when executing a Java application program. Prior java virtual machines typically load the predefined classes from class libraries contained in a local or a remote file system.

10

Unfortunately, such class loading may limit the applicability of such a software environment. For example, such a software environment may have limited applicability to embedded systems which may have little or no file system resources for storing the class libraries. In addition, the costs of providing the network access resources needed to load classes from remote class libraries and/or the costs of providing network servers to hold the remote class libraries may be prohibitively high for embedded systems.

15

20

SUMMARY OF THE INVENTION

A virtual machine is disclosed with mechanisms for class loading and class structure management in a device having limited file system and/or memory resources. The virtual machine includes a class loader that obtains one or more of a set of predefined classes from a network server, thereby reducing or eliminating the need for a local file system in the device. The class loader stores the predefined classes into a class structure in memory in the device. The virtual machine further includes a memory manager that purges selected ones of the predefined classes from the class structure so as to minimize an amount of the memory consumed by the predefined classes in the class structure and to minimize class loading activities via a network. The class loader uses network prevalent mechanisms such as HTTP to minimize costs of network class loading.

Other features and advantages of the present invention will be apparent from the detailed description that follows.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is described with respect to particular exemplary embodiments thereof and
5 reference is accordingly made to the drawings in which:

Figure 1 shows a virtual machine that enables execution of application programs in a device having
10 relatively limited resources;

Figure 2 shows one embodiment of a class loading method according to the present teachings;

Figure 3 illustrates a method for maintaining
15 optimal use of the memory resources that store classes being used by application programs;

Figure 4 shows an example hardware embodiment of
20 a device that benefits from the teachings provided herein.

DETAILED DESCRIPTION

5 **Figure 1** shows a virtual machine 12 that enables
execution of an application program 24 in a device 10
having relatively limited resources. The limited
resources of the device 10 may be characterized by
limited or non existent file system resources.
Alternatively or in addition, the limited resources
of the device 10 may be characterized by limited
10 memory resources.

15 The virtual machine 12 enables execution of one
or more application programs such as the application
program 24. The application program 24 is written to
invoke one or more of a set of predefined classes
that are supported by the virtual machine 12. The
virtual machine 12 loads these predefined classes
into a class structure 22 as needed during execution
of the application program 24. In one embodiment,
20 the predefined classes are Java classes and the
virtual machine 12 is a Java virtual machine.

25 The virtual machine 12 includes a class loader
16 that reduces or eliminates the need for providing
a file system in the device 10 by loading the
predefined classes via a network 30. In one
embodiment, the predefined classes are loaded from a
set of class files 28 contained on a network server
26. In other embodiments, the class files 28 may be
30 distributed among several network servers accessible
via the network 30.

5 The class loader 16 includes a network client 18
for accessing the network server 26 and an underlying
network protocol stack 20 for communicating with the
network server 26 via the network 30. The particular
10 protocol for communication between the network client
18 and the network server 26 is preselected so as to
minimize development and/or manufacturing costs
associated with the device 10. In one embodiment,
the network server 26 is a hyper-text transfer
15 protocol (HTTP) server and the network client 18 is
an HTTP client. The network protocol stack 20 in
this embodiment includes the TCP/IP layers and layers
that provide communication according to the
particular physical implementation of the connection
to the network 30.

20 The HTTP protocol may be preferred in that it is
widely used network prevalent protocol. As a
consequence, HTTP client and network protocol stacks
are readily available for a variety of platforms.
This helps minimize the cost and reduce the
development time and ease the implementation of the
virtual machine 12 in a variety of devices. For
example, the device 10 may be implemented using a
25 platform in which HTTP client and underlying layers
are readily available and need not be independently
developed. Moreover, the relatively low cost and
wide availability of existing HTTP servers offers
additional advantages. For example, the network
30 server 26 may be an existing HTTP server to which the
class files 28 are added to support the device 10.
This would eliminate the costs associated with

installing a network server which is dedicated to providing class files to the device 10.

The virtual machine 12 includes a memory manager 14 that minimizes the amount of memory resources needed in the device 10 to hold the predefined classes being used for execution of the application program 24. The memory manager 14 monitors the classes stored in the class structure 22 and purges selected ones of the classes from the class structure 22 so as to provide optimal use of the memory resources in the device 10. In addition, the memory manager 14 monitors the classes stored in the class structure 22 and purges selected ones of the classes from the class structure 22 so as to minimize the amount of class loading performed via the network 30.

The device 10 represents any device which may benefit from the advantages provided by the virtual machine 12. This may include devices with relatively little or no file system resources and or minimal memory resources. The device 10 may be an embedded system. Examples of embedded systems include telephones, audio and video equipment, home appliances, and computer peripherals.

Figure 2 shows one embodiment of a class loading method implemented in the class loader 16. The steps shown are performed by the class loader 16 in response to a request by the virtual machine 12 to load a particular class of the predefined classes that support execution of the application program 24.

The particular class may be, for example, a class having a method which is being invoked by the application program 24.

5 At step 50, the class loader 16 obtains a uniform resource locator (URL) for the network class files 28. In one embodiment, the appropriate URL or URLs for the network class files 28 are specified in one or more NETWORK CLASS PATH definition statements
10 which are provided to the virtual machine 12. An example NETWORK CLASS PATH definition statement is as follows.

15 NETWORK CLASS PATH="netserver/80"

 where "netserver/80" is a URL of the class files 28. The class files 28 are exported by the network server 26.

20 At step 52, the class loader 16 generates an HTTP GET command that specifies the particular class file being requested. The HTTP GET command is provided to the network client 18 which in turn issues the HTTP GET command to the network server 26
25 via the network protocol stack 20. An example of an HTTP GET command is as follows:

 GET "netserver/80/foo.class"

30 where "foo.class" is the particular class being loaded, and "netserver/80" is a URL specified in a NETWORK CLASS PATH definition statement. If multiple URLs are specified in NETWORK CLASS PATH definition statements then the class loader 16 generates an HTTP

GET command for each at step 52 until the particular
class file is found. The multiple URLs may be sub-
paths on one network server such as the network
server 26 or pathnames for multiple network servers
5 or any combination thereof.

In response to an HTTP GET command issued at
step 52, the network server 26 returns a data stream
containing the particular class file to the network
10 client 18. The network client 18 provides the
returned file data stream to the class loader 16 at
step 54.

At step 56, the class loader 16 converts the
15 class file data stream into a predefined class
definition format and loads it into the class
structure 22. In one embodiment, the predefined
class definition format includes arrays and tables
for storing methods and references or addresses to
20 the methods in accordance with the Java object-
oriented programming language. Thereafter, the
virtual machine 12 may create instances of the newly
loaded particular class for use by the application
program 24.

25

Figure 3 illustrates one embodiment of a method
implemented in the memory manager 14 for maintaining
optimal use of the memory resources in the device 10
that hold the class structure 22. The methods steps
30 shown may be performed periodically at predetermined
time intervals such as during system idle periods.
Alternatively or in addition, the methods steps shown
may be performed whenever it is detected that the

memory resources in the device 10 are below a predetermined threshold level of available memory.

At step 60, the memory manager 14 determines
5 which of a set of classes currently stored in the
class structure 22 is the least recently used class.
The virtual machine 12 may associate a time value to
each class contained in the class structure 22 that
indicates a time at which an instance of the
10 corresponding class was created. The memory manager
14 may select the least recently used class by
selecting on oldest of these time values.
Alternatively, count values or other metrics may be
used to indicate a relative ordering of the creation
15 of objects from the classes contained in the class
structure 22.

The memory manager 14 selects the least recently
used class as a candidate to purge from the class
20 structure 22. In this embodiment, a purging of the
least recently used class may minimize class loading
via the network 30 because more recently used classes
are more likely to be needed by the virtual machine
12 to create new objects. The need for subsequent
25 class loading operations on the more recently used
classes may be reduced if these classes are retained
in the class structure 22. In other embodiments,
other criteria for selecting classes as candidates
for purging may be employed. For example, certain
30 types of classes or classes that perform particular
types of functions are known to be relatively
infrequently invoked and may be selected at step 60.

At step 62, the memory manager 14 determines whether the class selected from step 60 is in use. The selected class is in use if it is associated with one or more objects being used by the application
5 program 24. For example, if an object used by the application program 24 is an instance of the selected class then the selected class is in use for the purposes of step 62. Similarly, if an object used by the application program 24 is an instance of a
10 subclass or a parent class of the selected class then the selected class is in use for the purposes of step 62. The virtual machine 12 may maintain a list that specifies the hierarchical associations, i.e. parent and child relationships, of the classes contained in
15 the class structure 22. The memory manager 14 may use this list of associations to render the determination at step 62.

If the selected class is in use at step 62 then
20 the memory manager performs step 64. At step 64, the memory manager 14 determines the next least recently used class and proceeds to step 62 to determine whether the next least recently used class is in use. The memory manager 14 loops through steps 62 and 64
25 until a candidate for purging is selected. The memory manager then proceeds to step 66 if an appropriate class can be selected.

At step 66, the memory manager 14 purges the
30 class selected at step 60 or 64 from the class structure 22. At step 68, the memory manager 14 deletes objects from memory that are associated with the purged class. The virtual machine 12 may

maintain a list of associations between the classes
contained in the class structure 22 and instances of
these classes, i.e. objects, contained in memory in
the device 10. The memory manager 14 may use this
5 list to locate objects to be deleted at step 68.

In an alternative embodiment, the memory manager
14 deletes the selected class and all of its
associated objects regardless of whether the selected
10 class is in use.

In addition, the memory manager 14 may provide a
function for explicitly deleting one or more classes
which is callable by application programs such as the
15 application program 24. This enables an application
program to clean up unneeded classes from memory.
This helps prevent unneeded classes from cluttering
what may be a relatively limited memory space in the
device 10.

20 **Figure 4** shows an example hardware embodiment of
the device 10 which includes a processor 96 for
executing the virtual machine 12 and the application
program 24 and other software or firmware associated
25 with the device 10. The limited memory resources for
holding classes that are being used by application
programs is represented by a memory 90 which is a
random access memory. The memory 90 holds the class
structure 22 and may hold the application program 24
30 and/or elements of the virtual machine 12 as well as
instances of classes including classes contained in
the class structure 22. Alternatively, the
application program 24 and/or elements of the virtual

machine 12 may be stored in a persistent memory (not shown) in the device 10.

5 In this embodiment, the limited file system resources of the device 10 are represented by a set of file system resources 92. The file system resources 92 may represent elements such as magnetic media including rotating media or solid-state devices or other storage mechanisms. In other embodiments, 10 the device 10 does not have any file system resources.

15 The device 10 also includes a set of network access resources 94. The network access resources 94 represent the appropriate hardware and software elements that enable communication via a network 30 using the hyper-text transfer protocol (HTTP). The physical communication path supported by network access resources 94 may be a communication link such as Ethernet, a wireless communication link including 20 infrared, a radio link including cellular radio, or a serial or parallel communication link depending on the nature and cost constraints associated with the design of the device 10.

25 The foregoing detailed description of the present invention is provided for the purposes of illustration and is not intended to be exhaustive or to limit the invention to the precise embodiment disclosed. Accordingly, the scope of the present 30 invention is defined by the appended claims.

CLAIMS

What is claimed is:

- 5 1. A virtual machine, comprising:
- class structure for holding one or more of a set
 of predefined classes for use by an application
 program that executes under the virtual machine;
 class loader that obtains one or more of the
10 predefined classes from a network server and that
 stores the predefined classes into the class
 structure;
- memory manager that purges selected ones of the
 predefined classes from the class structure so as to
15 optimize the use of memory resources consumed by the
 predefined classes in the class structure.
2. The virtual machine of claim 1, wherein the
 network server is an HTTP server that exports a set
20 of class files containing one or more of the
 predefined classes.
3. The virtual machine of claim 2, wherein the
 class loader includes an HTTP client that generates
25 an HTTP GET command that specifies a particular one
 of the class files and provides the HTTP GET command
 to the HTTP server in response to a request to load a
 particular one of the predefined classes.
4. The virtual machine of claim 3, wherein the HTTP
30 GET command specifies a URL for the particular one of
 the class files.

5. The virtual machine of claim 2, wherein the virtual machine is provided with a class definition statement that specifies one or more URLs for the class files.

5

6. The virtual machine of claim 1, wherein the memory manager purges a least recently used one of the predefined classes from the class structure if the least recently used class is not in use.

10

7. The virtual machine of claim 6, wherein the memory manager purges a next least recently used one of the predefined classes if the least recently used class is in use.

15

8. The virtual machine of claim 7, wherein the memory manager purges a set of objects associated with the least recently used or the next recently used one of the predefined classes purged from the class structure.

20

9. The virtual machine of claim 7, wherein the memory manager purges the least recently used or the next recently used one of the predefined classes at periodic times.

25

10. The virtual machine of claim 7, wherein the memory manager purges the least recently used or the next recently used one of the predefined classes if available memory resources fall below a predetermined threshold level.

30

11. The virtual machine of claim 7, wherein the memory manager purges the least recently used or the next recently used one of the predefined classes during system idle periods.

5

12. A method for class loading in a virtual machine, comprising the steps of:

obtaining one or more of a set of predefined classes from a network server;

10 storing the predefined classes into a class structure for use by an application program that executes under the virtual machine;

purging selected ones of the predefined classes from the class structure so as to optimize the use of memory resources consumed by the predefined classes in the class structure.

15

13. The method of claim 12, wherein the step of obtaining includes the step of generating an HTTP GET command that specifies a particular one of the class files and providing the HTTP GET command to an HTTP server in response to a request to load a particular one of the predefined classes.

20

14. The method of claim 13, wherein the step of purging includes the step of purging a least recently used one of the predefined classes from the class structure.

25

15. The method of claim 14, wherein the step of purging includes the step of purging a set of objects associated with the class purged from the class structure.

30

16. A device, comprising:
- memory that holds a class structure for storing one or more of a set of predefined classes for use by an application program;
- 5 processor that executes the application program and a class loader that when executed obtains one or more of the predefined classes from a network server and stores the predefined classes into the class structure for use when executing the application
- 10 program, the processor further executing a memory manager that when executed purges selected ones of the predefined classes from the class structure so as to optimize use of the memory.
- 15 17. The device of claim 16, wherein the memory manager is executed at periodic times.
18. The device of claim 16, wherein the memory manager is executed if available resources in the
- 20 memory falls below a predetermined threshold level.
19. The device of claim 16, wherein the memory manager is executed during system idle periods.

ABSTRACT

A virtual machine with mechanisms for class loading and class structure management in a device having limited file system and/or memory resources.

5 The virtual machine includes a class loader that obtains one or more of a set of predefined classes from a network server, thereby reducing or eliminating the need for a local file system in the device. The class loader stores the predefined

10 classes into a class structure in memory in the device. The virtual machine further includes a memory manager that purges selected ones of the predefined classes from the class structure so as to optimize the use of the memory consumed by the

15 predefined classes in the class structure.
